

WHAT ARE YOUR OPTIONS?

With so many different types of birth control out there, it's hard to keep them all straight. This little cheat sheet can help you learn about most of them, and then you and your doctor can decide what may work best for you.

Combination Pill¹

Pill that contains 2 hormones—estrogen and progestin. The hormones in the Pill work by delaying the release of eggs from the ovaries. The Pill also thickens cervical mucus so sperm can't easily pass through.

Female Condom¹

Plastic pouch inserted into the vagina with flexible rings at each end help it to stay in place during sex. It collects the sperm when a man ejaculates to keep it from entering the vagina and reaching an egg.

Male Condom¹

Thin latex or plastic covering worn on an erect penis during sex. A condom collects the sperm when a man ejaculates to keep it from entering the vagina and reaching an egg.

Ring¹

Small flexible ring that's inserted into the vagina to release estrogen and progestin. These hormones keep the ovaries from releasing eggs and thicken cervical mucus so sperm can't easily pass through.

Spermicides¹

Available in cream, film, foam, gel, or suppository form and inserted deep into the vagina. Spermicides contain a chemical that stops sperm from moving to keep them from joining an egg. Spermicides also block the opening to the uterus so that sperm can't reach an egg.

Intrauterine Device (IUD)¹

Small, T-shaped device inserted into the uterus by a healthcare provider. 2 types: 1 contains copper and 1 contains progestin, which keeps the ovaries from releasing eggs and thickens cervical mucus so sperm can't easily pass through. Both types change the lining of the uterus and affect the way sperm move to keep them from joining an egg.

Diaphragm¹

Shallow, dome-shaped, latex cup with a flexible rim that must be fitted by a healthcare provider. It goes inside the vagina to cover the cervix, blocking the opening to the uterus so sperm can't reach an egg.

Patch¹

Thin plastic patch that sticks to the stomach, butt, or upper body to release estrogen and progestin. These hormones keep ovaries from releasing eggs and thicken cervical mucus so sperm can't easily pass through.

Shot (Injection)¹

Shot that releases progestin into the body. Progestin works by keeping the ovaries from releasing eggs. The progestin in the shot also thickens cervical mucus so sperm can't easily pass through.
